INTRODUCTION

This is the updated projection of "baseline" or the "most likely" economic and demographic conditions through the year 2010 for the State of Utah, its counties, and its multi-county planning districts (MCD's) Rapidly changing economic and demographic circumstances in recent years have exacerbated the usual difficulties encountered when making long term projections. Despite these added uncertainties, an attempt has been made to quantify the changes that have occurred and develop new long term projections. While the projection process is improving, the uncertainty of the times makes it technically more difficult and, to an extent, decreases the reliability of the projections.

The primary purpose of this report is to make available to state agencies updated economic and demographic projections for planning and budgeting purposes, in an effort to achieve planning coordination. It is also hoped that local governments and private industry will utilize the projections to further achieve planning coordination.

The effort of producing population and employment projections is a continuous and evolving process. The annual updates are made based on empirical evidence of changing economic and demographic conditions. More specifically, updates are benchmarked to the latest employment estimates of the Utah Department of Employment Security, population estimates from the Utah Population Estimates Committee, birth and death data from the Bureau of Health Statistics and school enrollment data from the Utah Office of Education.

It should be noted however, that these projections are not based on current 1987 employment and population estimates but are based on 1986 final population and employment estimates. These projections were developed before final 1987 estimates were available. For this reason the short term projections may seem unrealistically high. *These projections are intended to provide a long-term perspective, which is relatively unaffected by the level at which they begin.* More reliable short-term projections for 1988 are 1,696,000 for population and 648,400 for wage and salary employment, which have been published in State of Utah Revenue Forecast, February 1988.

These projections reflect a "baseline projection," or a projection of the future based on the existing economic structure of the area and the changing demographic characteristics of the population. These economic and demographic conditions are projected into the future; in other words, a projection of the future is made by extrapolating the current trends. This is not a prediction or forecast of the future, but rather an attempt to depict the direction current trends are likely to take without major changes in the economic base.

These new projections were developed by using the Utah Process Economic and Demographic Model (UPED) -- the model the Office of Planning and Budget (OPB) has used for many years to generate population and employment impact projections (a more complete description of UPED is found in Appendix A).

What follows this narrative report are summary tables and figures which briefly describe and illustrate the projections to the year 2010 for Utah. Population data in this report represent estimates and projections as of July 1 of each year unless otherwise noted. More detailed projections are found in Appendices B and C. Further detailed information can be obtained by calling the Data Resources Section, Utah Office of Planning and Budget, (801) 538-1036. This projection information is also available in machine readable format.

STATE AND MULTI-COUNTY PLANNING DISTRICT (MCD) POPULATION GROWTH

Utah is projected to have almost one million more inhabitants in the year 2010 than were counted during the census in 1980. The projected population of 2,442,000 represents an average annual growth of 1.7 percent from 1980 to 2010. While this rate growth is significantly lower that Utah's rate of 2.5 percent from 1950 to 1980, it is still almost double the national growth rate for the same projection period. Figure 1 presents the average annual population growth rates for the state and MCD's. Table 1 presents the projections, along with the percentage distribution among MCD's and the total state population.

COMPONENTS OF STATE POPULATION CHANGE

Births

Population change in any area over time results from three phenomena: (1) Births, (2) Deaths, and (3) Net in- or out-migration. Utah's birth rate has historically been the highest in the nation. "Total fertility" (a measure of average births per woman) in Utah is still very high relative to the national average. However, Utah's rate has declined steadily during the 1980's, while the national rate has held fairly constant at about 1.8 births per woman (See Figure 2 and Table 2). After a historical comparison of Utah and U.S. fertility rates it seems reasonable to assume that the Utah total fertility rate will begin to stabilize at a level above that of the U.S. average. For the purpose of these projections, Utah's total fertility rate was assumed to decline to 2.5 births per woman by 1990 and then held constant for the remainder of the projection period.

Table 3 and Figure 3 show the expected natural increase (births minus deaths) for selected years. It is projected that 910,000 births will occur to Utah residents between 1987 and 2010. While the number of births is expected to taper off for the next few years, another surge of births is expected in the late 1990's as another generation begins to age into the childbearing years. Table 4 and Figure 4 show graphically the changing age structure of the state's population, and Table 5 and Figure 5 present the proportional distribution of the age cohorts.

Deaths

Not surprisingly, the number of deaths in the state is expected to rise continually through 2010 as is shown in Table 3, even though the survival rates for each age level are assumed to remain constant. The reason for this increase is that the population as a whole becomes more heavily concentrated in the older, lower survival rate age groups. For example, in 1980, 10.5 percent of the population was 60 years old or older, but this same age group is projected to increase to 14.2 percent of the population by 2010.

Net Migration

Migration is typically the most volatile component of population change because it varies with demographic changes and economic conditions. There was a period of net out-migration in the 1950's and into the 1960's, however net in-migration was experienced in Utah in every year from 1968 until 1983. We have now experienced four consecutive years of out-migration from Utah, totalling over 33,000 people.

During the period 1987 to 2010, over 180,000 net in-migration is expected to occur in the state (i.e., in-migration is expected to exceed out-migration by 180,000). Although out-migration is created when the economy is not growing fast enough to provide enough jobs for the growing labor force, population growth frequently occurs during these periods of net out-migration.

SCHOOL AGE POPULATION

Table 6 and Figure 6 present school age population (ages 5 through 17) growth. Although school age population is still increasing, it is expected to grow at an average of 1.2 percent per year from 1987 through 1993. This is substantially less growth than the 3.2 percent annual rate of growth experienced from 1980 to 1987. The decline in fertility rates, the age structure of women in the childbearing years, and the recent out-migration are responsible for the slowdown in the growth of the school age population. After 1993, there are nine consecutive years that are expected to show an actual decline in the school age population. In 2003 a new demographic growth cycle resumes as a result of women who began entering the childbearing years five years previously. Over the twenty three year period (1987-2010), school age population is projected to increase by over 65,000 children, an increase of 15 percent.

HOUSEHOLD FORMATION

Projections of the number of households in the state is produced by applying age and sex specific household formation probabilities to each year's population. These probabilities are held constant over the projection interval. They produce an increase in total households of over 400,000 for the 30 year projection period (Please see page B-1 in Appendix B). The lower fertility rate assumption, which results in fewer children, along with the projected aging of the population is reflected in the decline in average number of persons per household from 3.2 in 1980 to 2.75 in 2010.

EMPLOYMENT

Table 7 shows total state employment increasing from 617,300 jobs in 1980 to 1,188,000 jobs in 2010. This increase of over 570,000 jobs represents an average annual growth rate of 2.2 percent. Table 8 and Figures 7 and 8 show the changes in the industrial structure projected for Utah's job market. The overall pattern appears to be one of significant movement away from dependence on the state's traditional extractive-heavy manufacturing-government economic base and toward services and trade as driving sectors in the Utah economy. Appendix B presents employment projections by major industry for the state, and Appendix C presents these projections for the MCD's.

ASSUMPTIONS

Some of the major assumptions incorporated in Projections 1988 are as follows:

- Declining total fertility rates through 1990, and then held constant at 2.5 average births per woman (ages 15-44).
- Constant age specific mortality rates.
- Employment related migration concentrated in early adult ages.
- Constant age-sex specific household formation probabilities.
- Increases in overall female labor force participation rates.

Two other major categories of model driving assumptions concern industrial sector specific basic employment assumptions, and the relationships between number of people living in the state and the number of "residentiary" jobs located in the state to serve their needs. Please see Appendix A for a detailed discussion of UPED and its components.

In UPED, each of over 60 industrial sectors (agriculture, coal mining, chemical manufacturing, etc.) are separated into basic and residentiary components. Basic employment is analyzed and projected outside the model and is "fed" to the model as a major input. Residentiary employment, on the other hand, is produced within the model as a function of the number of people projected to be in the study area and of other inputs to the model.

Basic employment estimates by industrial sector for each MCD for the calibration year 1986 were produced to reflect actual 1986 employment levels. A major analytical and judgmental effort was subsequently carried out to project the future growth and/or decline of each industry through 2010. Two different approaches were utilized and their results were combined to produce the basic employment projections upon which these projections are based.

The first approach is based upon statistical analysis of historical employment data. Several different statistical models were specified as alternative hypothetical "explanations" of sector and MCD-specific employment histories. Some of the models attempted to use relationships of MCD to national employment levels and then national projections by industry were used to project MCD employment by industry. The results of each model were evaluated for goodness of fit and reasonableness of the basic employment projections produced by extending each model through the year 2010. For most sectors in most MCD's, one of the models provided both a good "explanation" of historical experience and reasonable projections of future basic employment growth or decline.

In many cases, however, dramatic alterations from past trends are virtually certain to occur over the next twenty three years. No statistical analysis of the past can reveal or capture the magnitude of such changes. Thus, a judgmental approach to basic employment projections was also carried out. This approach included an evaluation of proposed projects and events. This evaluation focused on three aspects of each event listed: (1) the likelihood of its actually occurring; (2) the basic, as opposed to residentiary, nature of the activity; and (3) the extent to which the event represents a real break from past trends as opposed to being part of normal growth projected as part of the statistical analysis described earlier.

COUNTY DISAGGREGATIONS

Regional population totals have been disaggregated to the county level. These projections are presented in Table 9 and Figure 9. As a result of the economic circumstances discussed earlier, the projections show that only seven counties in Utah will experience growth which will exceed the state average, while twenty-two counties will grow at the same rate or below the state average. The projections indicate that Washington, Davis and Morgan counties, are expected to be the fastest growing counties in Utah respectively over the next twenty three years, averaging at least two percent per year. The slowest growth, with an average of less than 1 percent growth per year, is projected to occur in Grand, Daggett, Emery, San Juan, Carbon, Piute, Rich, Juab, Wayne and Garfield counties respectively.

CONCLUSIONS

It can be discerned from this report that Utah can be expected to experience continued relatively good growth through the remainder of the 20th century and well into the 21st. The population growth rate in Utah is projected to be almost twice the growth projected for the nation. Although Utah will continue to be a growth state it will not experience the rapid growth rates of the past. Also, growth in Utah will not be evenly distributed across the state. In particular, the rural counties historically dependent on natural resource development appear to face the prospect of not being able to provide adequate jobs to employ all of their young people as they age into the labor force. Indeed, as has already been observed in the past few years, the entire state will experience periods of net out-migration as a result of inadequate employment opportunities. The overall state-level picture for most years, however, is one of adequate job growth to meet Utahns' employment needs, and of in-migration. The geographic distribution within the state of new jobs may cause in-migration from rural areas to metropolitan counties. Migration is extremely volatile and difficult to project and is subject to cycles in various industries. The expectations, as expressed in these projections are, of course, based on a set of crucial assumptions about future economic and demographic behavior. The assumptions have been summarized and discussed earlier, and they represent a consensus best effort of a large number of planners, officials, and analysts at both state and local levels. They are certainly plausible and reasonable as viewed from this point in time. Nonetheless, as all users and producers of such projections are constantly aware, some of them will prove to be wrong -- some badly wrong. The long term future of Utah is inherently difficult to predict.

APPENDIX A

COMPUTER MODEL

THE UTAH PROCESS ECONOMIC & DEMOGRAPHIC MODEL (UPED)

The Utah Process Economic and Demographic Impact Simulation Model (UPED) is the official model used by the Office of Planning and Budget to project population and employment growth in the state.* UPED is a hybrid of two standard population and economic projection methodologies: (1) the cohort survival model and (2) the economic base model. In the three-component, cohort survival population model, future population levels are projected from base year figures by adding births, subtracting deaths, and adding net in-migration or subtracting net out-migration. The values of each of the three components of population change (births, deaths, and migration) are projected as a function of the initial year values and the resultant increments are added or subtracted to generate the first projection year's values. The process is then repeated to generate the second projection year's values and so on to the last projection year. The population is disaggregated into appropriate sub-groups, called cohorts, whose values are projected over time. In UPED, sex and single year of age cohorts are used. Through the projection years, of course, each cohort ages and its behavior with respect to demand for goods and services, labor force participation, fertility, mortality, and geographic mobility varies with the aging process.

According to the economic base concept, for all but the largest (national-continental regions), the primary determinant of the level of economic activity, and consequently of population size, is the amount of goods and services produced for export to other areas. Increases or decreases in basic (export) employment produce corresponding changes in the number of households deriving their income from these sectors. These changes, in turn, produce changes in the demand for goods and services produced locally for the local consumption. (These local production-local consumption activities are referred to variously as non-basic, service, residentiary, or population dependent sectors). Initial changes in population dependent sectors in turn, produce changes in population and in household incomes which generate further changes until, finally, a given projected initial change in basic sector employment will produce a "multipliered" change in population dependent and local employment as well as in population.

In UPED, the economic base methodology is adapted to affect population projection through the migration component. Population projections, in turn, generate residentiary employment for each level of basic employment. Thus the cohort survival and economic base methodologies are combined in UPED to form a complex systems model. The workings of the UPED Model and of its key data requirements are presented in Figure A-1. The top three boxes represent the natural increase (births and deaths), aging, and the non-employment related part of the migration components of UPED's population project methodology.

The initial (Year t) population, consisting of a census-type count or estimate of all people residing in the area by age and sex is adjusted to reflect the temporary absence of some individuals who are permanent residents (an increase) and/or the temporary presence of individuals who are not permanent residents (a decrease). Relevant categories here include college students, military, and LDS missionaries. The resultant estimate of the permanent resident population is then survived by applying cohort specific survival rates.

Yearly Updated Feedback Relationships

The result is the subset of the initial resident population expected to still be alive the next year. Members of each cohort have aged one year. The aged-survived population is adjusted to reflect projected levels of temporary absence (a decrease) or presence (an increase) and permanent non-employment related in-(increase) and out-(decrease) migration. Total births are projected by applying a vector of age specific birth rates to the female component of this adjusted aged-survived population. Infants' sex composition and infant mortality are also projected at this stage. The result of these calculations, as shown in Box 3, is the Adjusted Natural Increase Population at Year t+l, which becomes the initial estimate of population in that year (Box 4).

This first approximation population projection is the source of two elements of Labor Market Analysis: (l) the initial (pre-employment related migration) Labor Force and (2) initial Population Dependent Job Opportunities at Year t+l (Boxes 5 and 6, respectively). The Labor Force is derived by applying projected age and sex specific labor force participation rates to the projected population. The projected participation rates are dependent upon both extrapolations of their secular trends and year-to-year changes in area economic opportunity.

Population dependent job opportunities are projected as dependent upon (l) the size and age composition of the population, (2) projected sector specific ratios of area per capita residentiary employment to national employment per capita, and (3) projections of national residentiary employment by sector and/or national population by cohort. Thus, changes in the size and/or demographic composition of the population, in the capability of the area to produce goods and services for its own consumption, and/or national economic and demographic conditions can all influence the projection of each sectors population dependent job opportunities. The most critical operational assumptions here are the local-national per capita residentiary employment relatives. Of special importance is the ability to adjust these assumptions to reflect structural changes as market expansion leads to import substitution possibilities.

As Box 7 indicates, basic employment demand is exogenously projected by sector and treated parametrically in UPED. These projections of basic employment are varied to reflect the different economic developments to be analyzed. For example, to project the impacts of a particular power plant, the direct basic employment by industrial sector involved in constructing and operating the plant would be added to a baseline basic employment projections and the sum would serve as the basic job opportunities input for that power plant's UPED run.

Basic and population dependent job opportunities are summed to produce Total Job Opportunities at Year t+l (Box 8). This, initial value for both the supply of and demand for labor are introduced into the Labor Market component of UPED, where they are used to calculate the projected unemployment rate as an index of the area's economic opportunities. This rate is compared against a parametrically established "normal" range of unemployment rates. If it is higher than the upper bound of the range -- the out-migration triggering rate -- this is taken to indicate inadequate opportunities for the natural increase population and Employment related Out-Migration at t+l is projected. Alternatively, if it is below the lower bound -- the in-migration triggering prosperity is indicated and Employment Related In-Migration at Year t+l is projected.

The amount of migration projected is sufficient to provide the labor force required to adjust the unemployment rate to the relevant triggering rate, assuming no change in population dependent job opportunities. The demographic detail of this migration reflects cohort difference in (l) labor force participation rates, (2) migration propensities, and (3) the composition of the source population (local population for out-migration, national population for in-migration).

Of course, the assumption stressed in the previous paragraph, that job opportunities do not change as a result of migration, is invalid. The migration of workers and their families either increases or decreases population dependent job opportunities. This first round migration will prove insufficient to adjust the unemployment rate to the relevant bound of normal range, and further migration in the same direction must be projected. The short dash arrows in Figure A-1 indicate the iterative nature of the UPED solution to this interdependence problem. The iterative process continues until the calculated unemployment rate is satisfactorily close to the relevant triggering rate, at which time solution is achieved and no further migration or employment changes are calculated. Final population, migration, and employment outputs are presented with the former being used to derive projections of households, labor force, and school age population. The solution value for projected population is then fed back into the Model (long dash arrow in Figure A-1) to serve as the initial population vector for the next projection year.

INTRODUCTION

This is the updated projection of "baseline" or the "most likely" economic and demographic conditions through the year 2010 for the State of Utah, its multi-county planning districts (MCDs) and its counties. Rapidly changing economic and demographic circumstances in recent years have exacerbated the usual difficulties encountered when making long-term projections. Despite these added uncertainties, an attempt has been made to quantify the changes that have occurred and develop new long-term projections. While the projection process is improving, the uncertainty of the times makes it technically more difficult and, to an extent, decreases the reliability of the projections.

The primary purpose of this report is to make available to state agencies updated economic and demographic projections for planning and budgeting purposes, in an effort to achieve planning coordination. It is also hoped that local governments and private industry will utilize the projections to further achieve planning coordination.

The effort of producing population and employment projections is a continuous and evolving process. This update is based on empirical evidence of changing economic and demographic conditions. More specifically, updates are benchmarked to the latest employment estimates of the Utah Department of Employment Security, population estimates from the Utah Population Estimates Committee, birth and death data from the Bureau of Health Statistics and school enrollment data from the Utah Office of Education.

Six months prior to the 1990 Census may seem like an unlikely time to produce new projections. However, this timing actually provides an ideal situation for evaluating methodology. All projections will be evaluated against the 1990 Census and methodologies analyzed accordingly. Also, all major parameters will be re-estimated based on research of the Census information and a major model recalibration completed. New projections from this process will be published in 1992-1993. The projections in this report will be the last published until then. However, short-term forecasts of statewide employment and populationwill continue to be published quarterly in the Utah State Data Guide.

These projections reflect a "baseline projection," or a projection of the future based on the existing economic structure of the area and the changing demographic characteristics of the population. These economic and demographic conditions are projected into the future; in other words, a projection of the future is made by extrapolating the current trends. This is not a prediction or forecast of the future, but rather an attempt to depict the direction current trends are likely to take without major changes in the economic base. The projections in this report are intended to provide a long-term perspective, which is relatively unaffected by the level at which they begin.

These new projections were developed using the Utah Process Economic and Demographic Model (UPED) -- the model the Office of Planning and Budget (OPB) has used for many years to generate population and employment impact projections (a more complete description of UPED is found in Appendix A, Part 1). There is a substantial addition to this edition of the projections report -- county-level demographic projections have been produced. These projections were made possible by the development of a new model - County Age and Sex Allocation (CASA). The development of this modeling capability and calibration of this model has been evolving over the past five years. A brief description of this model may be found in Appendix A, Part 2.

These projections show slightly lower (approximately 4% in the year 2010) population projections for the state as a whole than the last set of projections published. Even though projections are lower on the state level, there are some individual multi-county districts which show more growth than the last report, while others show less growth. This is primarily due to lower economic growth rates of the 1980's, which created a lower starting point and affects the long-term data base used to make the projections. However, Utah will still experience growth rates larger than the U.S., and larger than most other states.

The following is a summary of the long-term projections for Utah relative to the rest of the nation:

> The total fertility rate of Utah women is assumed to remain constant at approximately 2.5 average births per woman throughout her childbearing years. Total fertility rates nationally are projected to remain in the 1.8 to 1.9 range.
>
> Due to lower fertility and lower economic growth, the projected rates of population and employment growth are not only lower than previous projections, but significantly lower than growth rates of some earlier decades.
>
> Projected rates of population growth in Utah are higher than the rest of the nation. Utah is projected to have a 1.6 percent rate of growth between now and 2010 while the nation is projected to growth at less than half that rate.
>
> Utah's population projections indicate that the state would be the ninth fastest growing state in the U.S. during the decade of the 1980's and the eighth fastest growing state in the 1990's.
>
> Utah ranked thirty-sixth among all 50 states in population in 1980 and is expected to rise to thirty-fourth place by the year 2000.
>
> Utah is projected to continue to have the youngest population in the nation. Utah's median age in the year 2010 is projected to be 29 years, while the nation's median age is projected to be 39 years.
>
> The differences in age between Utah and the U.S. are projected to actually increase over the next two decades.
>
> Utah school age population will continue to grow over the next four years. It will then peak and begin to decline until the year 2003, when it begins to increase again. The temporary decline in this age group is primarily due to Utah's declining fertility rate. However, Utah will still have a nine percent increase in school age population during the

> period 1988-2010, while the national growth rate will be less than one percent.
>
> Utah's labor force will see periods of rapid increase over the next two decades. Utah will continue to have the youngest labor force in the nation. Nationally, labor shortages are occurring now in many parts of the U.S. and will become more prevalent in the future.
>
> The current out-migration is not expected to continue every year for the next two decades. However, the large increase in the labor force will create periods of some out-migration in Utah's future unless job growth is larger than has been historically experienced.

This narrative report is followed by summary tables and figures which briefly describe and illustrate the projections to the year 2010 for Utah. More detailed projections are found in the following appendices: Appendix B for state level, Appendix C for MCD level, and Appendix D for county level projections. Further detailed information can be obtained by calling the Demographic & Economic Analysis Section, Utah Office of Planning and Budget, (801) 538-1036. This projection information is also available in machine readable format.

STATE POPULATION GROWTH

Utah is projected to have almost one million more inhabitants in the year 2010 than were counted during the census in 1980. The projected population of 2,346,000 represents an average annual growth of 1.6 percent from 1980 to 2010. While this rate growth is significantly lower that Utah's rate of 2.5 percent from 1950 to 1980, it is still double the national growth rate for the same projection period. Figure 1 presents the average annual population growth rates for the state and counties. Table 1 presents the projections, along with the percentage distribution among MCDs and the total state population.

COMPONENTS OF STATE POPULATION CHANGE

Births

Population change in any area over time results from three phenomena: (1) Births, (2) Deaths, and (3) Net in- or out-migration. Utah's birth rate has historically been the highest in the nation. "Total fertility" (a measure of average births per woman) in Utah is still very high relative to the national average. However, Utah's rate has declined steadily during the 1980's, while the national rate has held fairly constant at about 1.8 births per woman (See Figure 2 and Table 2). After a historical comparison of Utah and U.S. fertility rates it seems reasonable to assume that the Utah total fertility rate will stabilize at a level above that of the U.S. average. For the purpose of these projections, Utah's total fertility rate was assumed to remain constant at approximately 2.5 births per woman through the projection period.

Table 3 and Figure 3 show the expected natural increase (births minus deaths) for selected years. It is projected that 840,000 births will occur to Utah residents between 1988 and 2010. The number of births is expected to taper off for the next few years, and then another surge of births is expected in the late 1990's as another generation begins to age into the childbearing years. Table 4 and Figure 4 show graphically the changing age structure of the state's population.

Deaths

Not surprisingly, the number of deaths in the state is expected to rise continually through 2010 as is shown in Table 3, even though the survival rates for each age level are assumed to remain constant. The reason for this increase is that the population as a whole becomes more heavily concentrated in the older, lower survival rate age groups. For example, in 1980, 10.5 percent of the population was 60 years old or older, but this same age group is projected to increase to 14.2 percent of the population by 2010.

Net Migration

Migration is typically the most volatile component of population change because it varies with demographic changes and economic conditions. There was a period of net out-migration in the 1950's and into the 1960's, however net in-migration was experienced in Utah in every year from 1968 until 1983. We have now experienced five consecutive years of out-migration from Utah (1984 to 1988), totalling over 41,000 people.

During the period 1988 to 2010, over 136,000 net in-migration is expected to occur in the state (i.e., in-migration is expected to exceed out-migration by 136,000). Although out-migration is created when the economy is not growing fast enough to provide enough jobs for the growing labor force, population growth frequently occurs during these periods of net out-migration.

SCHOOL AGE POPULATION

School age population (ages 5 - 17) is presented in Table 5 and Figure 5. Although school age population is still increasing, it is expected to grow at an average of less than 1 percent per year from 1988 through 1993. This is substantially less growth than the 3.2 percent annual rate of growth experienced from 1980 to 1987. The decline in fertility rates the age structure of women in the childbearing years and the recent out-migration are responsible for the slowdown in the growth of the school age population. After 1993, there are nine consecutive years that are expected to show an actual decline in the school age population. In 2003 growth resumes, as a new demographic cycle begins when larger age cohorts of women enter the childbearing years. Between 1988 and 2010, school age population is projections in increase by almost 40,000 children, an increase of 9 percent.

HOUSEHOLD FORMATION

Projections of the number of households in the state is produced by applying age and sex specific household formation probabilities to each year's population. These probabilities are held constant over the projection interval. They produce an increase in total households of over 340,000 for the 22 year projection period (Please see Table B-1 in Appendix B). The lower fertility rate assumption, which results in fewer children, along with the projected aging of the population is reflected in the decline in average number of persons per household from 3.2 in 1980 to 2.74 in 2010.

EMPLOYMENT

Table 6 shows total state employment increasing from 617,300 jobs in 1980 to 1,225,000 jobs in 2010. This increase of over 600,000 jobs represents an average annual growth rate of 2.3 percent. Table 7 and Figures 6 and 7 show the changes in the industrial structure projected for Utah's job market. The overall pattern appears to be one of significant movement away from dependence on the state's traditional extractive-heavy manufacturing-government economic base and toward services and trade as driving sectors in the Utah economy. Appendix B presents employment projections by detail industry for the state, Appendix C presents the projections by major industry for the MCDs, and Appendix D presents total employment projections by county.

The more specific industries (2-digit SIC code) which are projected to have the fastest growth rates are:

machinery and electronic equipment
air transportation
transportation services
hotels and lodging
business services
health services

ASSUMPTIONS

Some of the major assumptions incorporated in Projections 1990 are as follows:

- Fertility rates held constant at 2.5 average births per woman (ages 15-44).
- Constant age specific mortality rates.
- Employment related migration concentrated in early adult ages.
- Constant age-sex specific household formation probabilities.
- A significant increase in overall female labor force participation rates.

Two major categories of model driving assumptions concern industrial sector specific basic employment assumptions, and the relationships between number of people living in the state and the number of "residentiary" jobs located in the state to serve their needs. Please see Appendix A, Part 1, for a detailed discussion of UPED and its components.

In many cases dramatic alterations from past trends are virtually certain to occur over the next twenty years. No statistical analysis of the past can reveal or capture the magnitude of such changes. Thus, a judgmental approach to basic employment projections was also carried out. This approach included an evaluation of proposed projects and events. This evaluation focused on three aspects of each event listed: (1) the likelihood of its actually occurring; (2) the basic, as opposed to residentiary, nature of the activity; and (3) the extent to which the event represents a real break from past trends as opposed to being part of normal growth projected as part of the statistical analysis described earlier.

CONCLUSIONS

Utah can be expected to experience continued relatively good growth through the remainder of the 20th century and well into the 21st. The population growth rate in Utah is projected to be twice the growth projected for the nation. Although Utah will continue to be a growth state it will not experience the rapid growth rates of the past. Also, growth in Utah will not be evenly distributed across the state. In particular, the rural counties historically dependent on natural resource development appear to face the prospect of not being able to provide adequate jobs to employ all of their young people as they age into the labor force. Indeed, as has already been observed in the past few years, the entire state will experience periods of net out-migration as a result of inadequate employment opportunities. The overall state-level picture for most projections years is one of adequate job growth to meet Utahns' employment needs. The geographic distribution within the state of new jobs may cause in-migration from rural areas to metropolitan counties. Migration is extremely volatile and difficult to project and is subject to cycles in various industries. The expectations, as expressed in these projections are, of course, based on a set of crucial assumptions about future economic and demographic behavior. The assumptions have been summarized and discussed earlier, and they represent a consensus best effort of a large number of planners, officials, and analysts at both state and local levels. They are plausible and reasonable as viewed from this point in time.

APPENDIX A

COMPUTER MODELS

PART I - UTAH PROCESS ECONOMIC & DEMOGRAPHIC MODEL (UPED)

PART II - COUNTY AGE & SEX ALLOCATION MODEL (CASA)

PART I: THE UTAH PROCESS ECONOMIC & DEMOGRAPHIC MODEL (UPED)

The Utah Process Economic and Demographic Impact Simulation Model (UPED) is the official model used by the Office of Planning and Budget to project population and employment growth in the state.* UPED is a hybrid of two standard population and economic projection methodologies: (1) the cohort survival model and (2) the economic base model. In the three-component, cohort survival population model, future population levels are projected from base year figures by adding births, subtracting deaths, and adding net in-migration or subtracting net out-migration. The values of each of the three components of population change (births, deaths, and migration) are projected as a function of the initial year values and the resultant increments are added or subtracted to generate the first projection year's values. The process is then repeated to generate the second projection year's values and so on to the last projection year. The population is disaggregated into appropriate sub-groups, called cohorts, whose values are projected over time. In UPED, sex and single year of age cohorts are used. Through the projection years, of course, each cohort ages and its behavior with respect to demand for goods and services, labor force participation, fertility, mortality, and geographic mobility varies with the aging process.

According to the economic base concept, for all but the largest (national-continental regions), the primary determinant of the level of economic activity, and consequently of population size, is the amount of goods and services produced for export to other areas. Increases or decreases in basic (export) employment produce corresponding changes in the number of households deriving their income from these sectors. These changes, in turn, produce changes in the demand for goods and services produced locally for the local consumption. (These local production-local consumption activities are referred to variously as non-basic, service, residentiary, or population dependent sectors). Initial changes in population dependent sectors in turn, produce changes in population and in household incomes which generate further changes until, finally, a given projected initial change in basic sector employment will produce a "multipliered" change in population dependent and local employment as well as in population.

In UPED, the economic base methodology is adapted to affect population projection through the migration component. Population projections, in turn, generate residentiary employment for each level of basic employment. Thus, the cohort survival and economic base methodologies are combined in UPED to form a complex systems model. The workings of the UPED Model and of its key data requirements are presented in Figure A-1. The top three boxes represent the natural increase (births and deaths), aging, and the non-employment related part of the migration components of UPED's population project methodology.

The initial (Year t) population, consisting of a census-type count or estimate of all people residing in the area by age and sex is adjusted to reflect the temporary absence of some individuals who are permanent residents (an increase) and/or the temporary presence of individuals who are not permanent residents (a decrease). Relevant categories here include college students, military, and LDS missionaries. The resultant estimate of the permanent resident population is then survived by applying cohort specific survival rates.

Yearly Updated Feedback Relationships

The result is the subset of the initial resident population expected to still be alive the next year. Members of each cohort have aged one year. The aged-survived population is adjusted to reflect projected levels of temporary absence (a decrease) or presence (an increase) and permanent non-employment related in-(increase) and out-(decrease) migration. Total births are projected by applying a vector of age specific birth rates to the female component of this adjusted aged-survived population. Infants' sex composition and infant mortality are also projected at this stage. The result of these calculations, as shown in Box 3, is the Adjusted Natural Increase Population at Year t+l, which becomes the initial estimate of population in that year (Box 4).

This first approximation population projection is the source of two elements of Labor Market Analysis: (l) the initial (pre-employment related migration) Labor Force and (2) initial Population Dependent Job Opportunities at Year t+l (Boxes 5 and 6, respectively). The Labor Force is derived by applying projected age and sex specific labor force participation rates to the projected population. The projected participation rates are dependent upon both extrapolations of their secular trends and year-to-year changes in area economic opportunity.

Population dependent job opportunities are projected as dependent upon (l) the size and age composition of the population, (2) projected sector specific ratios of area per capita residentiary employment to national employment per capita, and (3) projections of national residentiary employment by sector and/or national population by cohort. Thus, changes in the size and/or demographic composition of the population, in the capability of the area to produce goods and services for its own consumption, and/or national economic and demographic conditions can all influence the projection of each sectors population dependent job opportunities. The most critical operational assumptions here are the local-national per capita residentiary employment relatives. Of special importance is the ability to adjust these assumptions to reflect structural changes as market expansion leads to import substitution possibilities.

As Box 7 indicates, basic employment demand is exogenously projected by sector and treated parametrically in UPED. These projections of basic employment are varied to reflect the different economic developments to be analyzed. For example, to project the impacts of a particular power plant, the direct basic employment by industrial sector involved in constructing and operating the plant would be added to a baseline basic employment projections and the sum would serve as the basic job opportunities input for that power plant's UPED run.

Basic and population dependent job opportunities are summed to produce Total Job Opportunities at Year t+l (Box 8). This, initial value for both the supply of and demand for labor are introduced into the Labor Market component of UPED, where they are used to calculate the projected unemployment rate as an index of the area's economic opportunities. This rate is compared against a parametrically established "normal" range of unemployment rates. If it is higher than the upper bound of the range -- the out-migration triggering rate -- this is taken to indicate inadequate opportunities for the natural increase population and Employment related Out-Migration at t+l is projected. Alternatively, if it is below the lower bound -- the in-migration triggering prosperity is indicated and Employment Related In-Migration at Year t+l is projected.

The amount of migration projected is sufficient to provide the labor force required to adjust the unemployment rate to the relevant triggering rate, assuming no change in population dependent job opportunities. The demographic detail of this migration reflects cohort difference in (l) labor force participation rates, (2) migration propensities, and (3) the composition of the source population (local population for out-migration, national population for in-migration).

Of course, the assumption stressed in the previous paragraph, that job opportunities do not change as a result of migration, is invalid. The migration of workers and their families either increases or decreases population dependent job opportunities. This first round migration will prove insufficient to adjust the unemployment rate to the relevant bound of normal range, and further migration in the same direction must be projected. The short dash arrows in Figure A-1 indicate the iterative nature of the UPED solution to this interdependence problem. The iterative process continues until the calculated unemployment rate is satisfactorily close to the relevant triggering rate, at which time solution is achieved and no further migration or employment changes are calculated. Final population, migration, and employment outputs are presented with the former being used to derive projections of households, labor force, and school age population. The solution value for projected population is then fed back into the Model (long dash arrow in Figure A-1) to serve as the initial population vector for the next projection year.

PART II: COUNTY AGE AND SEX ALLOCATION MODEL (CASA)

There has been a growing demand for county-level age and sex-specific population projections in Utah. The development of a modeling procedure to produce these county population projections has been a long time in the process. The CASA (County Age and Sex Allocation) model combines with UPED to provide these projections.

CASA receives as input MCD-level population projections by sex and single year of age produced by UPED or a similar model, consistent projections of total population at the county level, and a number of other inputs. From there, it produces an age and sex specific allocation of the county level total population projections which is consistent with the MCD-level age and sex detail projections, with base year county demographic detail, and with projected birth, death and migration behaviors at the MCD level.

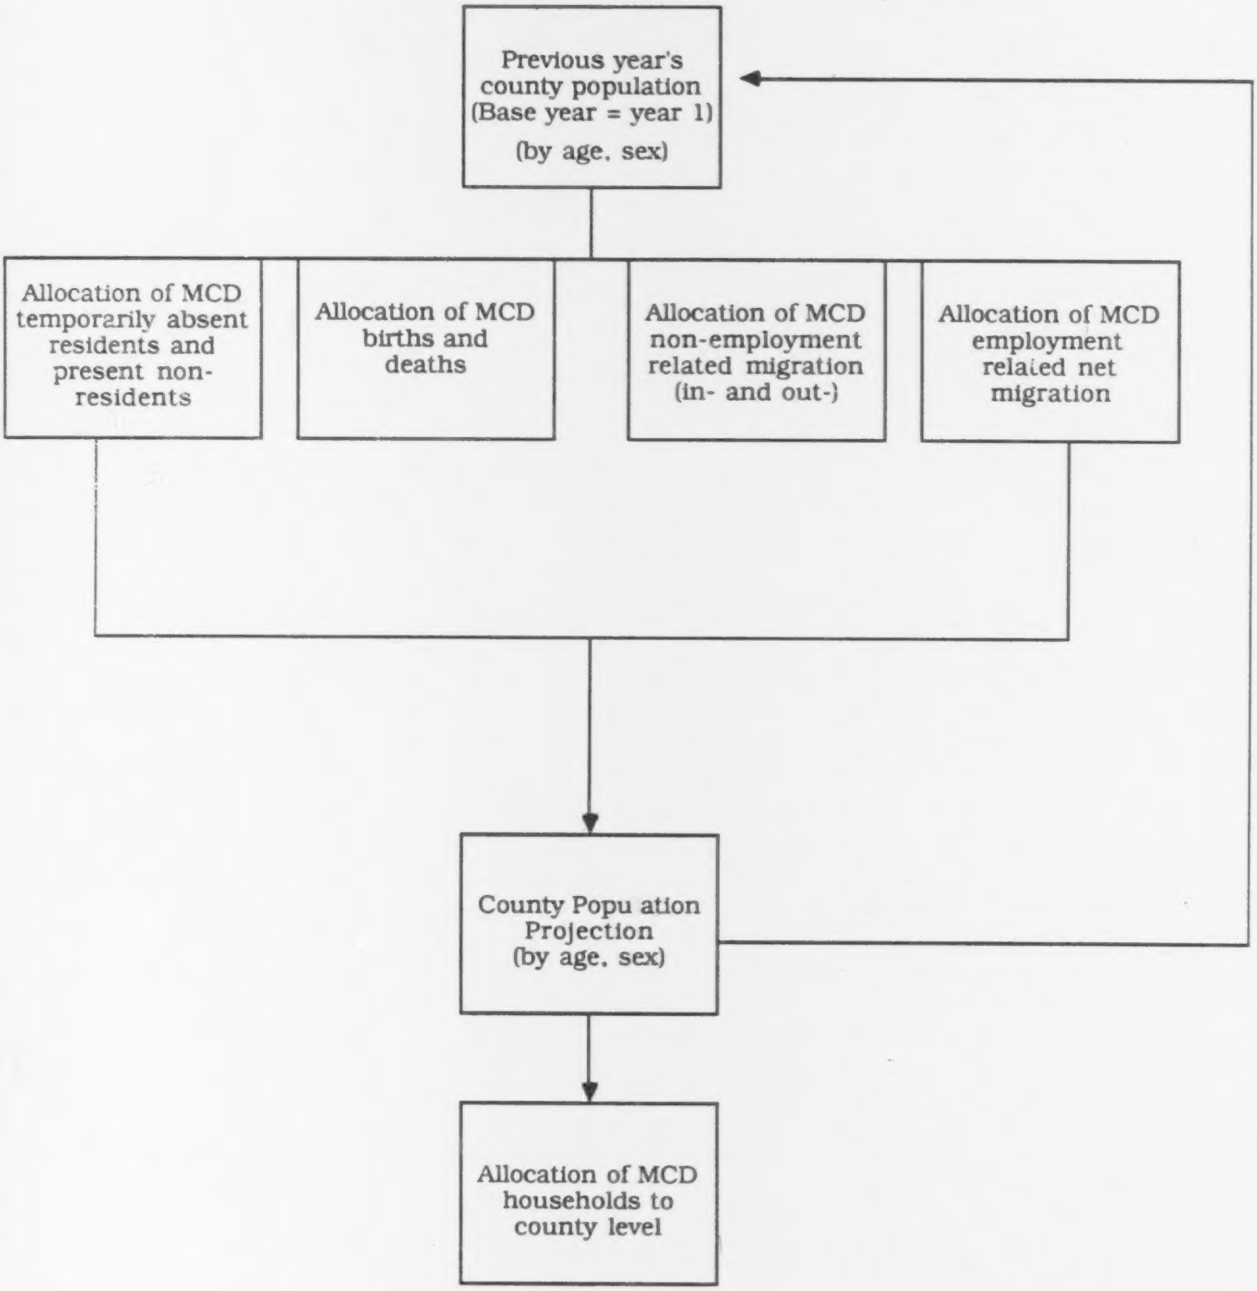
A number of theoretical difficulties were addressed in developing CASA. First, counties comprising any MCD generally experience varying historical growth and decline patterns. Some counties have grown, while others have declined or stagnated during the same historical periods. Further, different counties have experienced different time paths of growth, stagnation, and decline. As a result, in any one year, counties usually exhibit wide variation in their populations' age and sex compositions. This base year variation imposes one of the chief theoretical difficulties in allocating MCD-level projected age-sex compositions among county-level total population projections. A related theoretical difficulty is imposed by the necessity of allowing for the inevitable cases of some counties being projected to grow while others in the same MCD stagnate or decline. The model must account for growing counties in stagnating or declining MCDs and for declining counties in growing MCDs.

The problems discussed above dictate the adoption of the component cohort survival approach for allocating the county level total population projections across age and sex groups consistently with UPED's MCD level age and sex specific population projections. Thus, CASA employs the same general demographic approach as does UPED. Each county's base year population is specified in full sex and single year of age detail. Each cohort is aged and survived one year at a time through the projection horizon. Also, each cohort either receives in-migration or contributes out-migration each year. Each year's final projected age and sex specific population projection becomes a basic input in the next year's projection. Each element - births, deaths, non-employment related gross migration, and employment related net migration - of each year's county level cohort survival process is computed as an allocation of a corresponding MCD-level element or set of elements.

The most complex component of CASA is the procedure for allocating MCD-level projections of employment related migration . The complexity of this component of the model results from the fact that some counties may experience net migration flows in a direction opposite to that of the MCD as a whole; i.e. some counties may experience net out-migration in a period in which the MCD of which they are a part is experiencing in-migration. The result of counter-flow is a general tendency for the counter-flow counties' age and sex structures to diverge from those of the MCD as a whole and more so to diverge from the structures of the counties whose net migration flows are in the same direction as the MCD.

The final age and sex specific population projections for each county for the current projection year sum to the total county population projection. The sum across counties of each age-sex group equals the corresponding MCD level age-sex specific projection from UPED. The procedures used to produce these projections impose consistency with

CASA MODEL GENERAL FLOW CHART



Previous year's county population (Base year = year 1) (by age, sex)
Allocation of MCD temporarily absent residents and present non-residents
Allocation of MCD births and deaths
Allocation of MCD non-employment related migration (in- and out-)
Allocation of MCD employment related net migration
County Population Projection (by age, sex)
Allocation of MCD households to county level

established demographic behaviors regarding fertility, mortality, non-employment related migration and employment related migration. Thus, consistency with each year's MCD-level demographic detail is maintained while producing county demographic structures which sum to the specified totals each year, but which exhibit the expected variations across counties within the MCD, and which vary in response to varying MCD and county level projection scenarios.

(1) Transportation, Communication, and Public Utilities
(2) Finance, Insurance, and Real Estate
(3) Services includes Private Household employees
(4) Bureau of Economic Analysis (BEA) definition and accounting methods changed in 1987, resulting in a much larger NFP count than in previous years
(5) Total may not add due to rounding

TABLE B-4

STATE OF UTAH AND UNITED STATES MEDIAN AGE SELECTED YEARS 1980-2010

YEAR	UTAH	UNITED STATES
1980	24	30
1986	25	32
1990	25	33
1995	26	35
2000	27	36
2005	28	38
2010	29	39

TABLE B-5

DEPENDENCY RATIOS FOR UTAH
Selected Years

		1980	1990	1995	2000	2005	2010
Dependency Ratio *	**Utah**	80	82	78	70	67	68
	U.S.	65	61	62	60	57	56
Children 0-4 Per 100 Adults (Age 18-64)	**Utah**	24	18	16	16	16	16
	U.S.	12	12	11	10	9	9
School Children 5-17 Per 100 Adults (Age 18-64)	**Utah**	43	47	44	37	34	34
	U.S.	34	29	30	29	27	25
Adults 65+ Per 100 Adults (Age 18-64)	**Utah**	13	17	18	18	17	18
	U.S.	19	20	21	21	21	22

*The dependency ratio is defined to be the number of children ages 0-17
and adults ages 65+ (retirees) per 100 persons of working age, 18-64 years of age.

(1) Transportation, Communication, and Public Utilities
(2) Finance, Insurance, and Real Estate
(3) Services includes Private Household employees
(4) Bureau of Economic Analysis (BEA) definition and accounting methods changed in 1987, resulting in a much larger NFP count than in previous years
(5) Total may not add due to rounding

(1) Transportation, Communication, and Public Utilities
(2) Finance, Insurance, and Real Estate
(3) Services includes Private Household employees
(4) Bureau of Economic Analysis (BEA) definition and accounting methods changed in 1987, resulting in a much larger NFP count than in previous years
(5) Total may not add due to rounding

NOTE: Totals may not add due to rounding.

(1) Total Employment includes Agriculture and Non-Farm Proprietors (NFPs) employment.

(2) Bureau of Economic Analysis (BEA) definition and accounting methods changed in 1987, resulting in a much larger NFP employment count, and therefore a larger employment total, than in previous years.

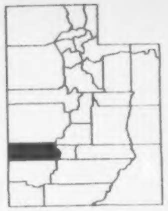

TABLE D-2

BEAVER COUNTY DEMOGRAPHIC SUMMARY
1989-2010

YEAR	POPULATION	SCHOOL AGE POPULATION	65 + POPULATION	HOUSEHOLDS	AVERAGE HOUSEHOLD SIZE
1989	4,900	1,400	750	1,500	3.25
1990	5,000	1,450	750	1,550	3.22
